Biological Control of Noxious Weeds

Biological controls are one of the methods available to the Colorado Department of Transportation (CDOT) for controlling the spread of noxious weeds along State Highway corridors. Biological control is the intentional use of a living agent to reduce the population of an undesirable pest. The types of biological agents used to control noxious weeds include:

- Insects, such as beetles, moths and flies
- Diseases, such as rusts and fungus
- Vertebrates, such as goats, sheep, and cows

Properly tested and approved biological control will feed on only the targeted weed species, and will not move on to attack any other plant.
